dPETSTEP

- Run your first simulation -

Introduction

dPETSTEP (https://github.com/CRossSchmidtlein/dPETSTEP) is a fast dynamic PET simulator designed for high throughput simulation of dynamic PET images. It allows full simulation of a user defined parametric image, kinetic model, input function, time sampling and more into realistic (noisy) dynamic PET-like images. Furthermore, the dynamic PET data can then be model fitted to produce parameter/parametric image estimates.

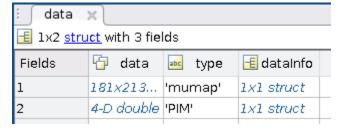

This application is written in MATLAB and designed as an extension of PETSTEP (https://github.com/CRossSchmidtlein/PETSTEP). Currently, MATLAB functions from PETSTEP are used by dPETSTEP, but there is no requirement of installing CERR (Computational Environment for Radiological Research, https://github.com/adityaapte/CERR).

Data structure

The data used by dPETSTEP should have a certain format, as will be specified below. It should contain three fields: data, type and dataInfo. It should contain two rows per field:

- 1. The first row should be the CT or mu-map of the object. Data should contain the 3D matrix of the object. Type should be "CT" or "mumap".
- 2. The second row should be the parametric image of the object. Data should be the 4D (3 spatial + 1 parametric) matrix with the parametric object. Type should be "PIM".

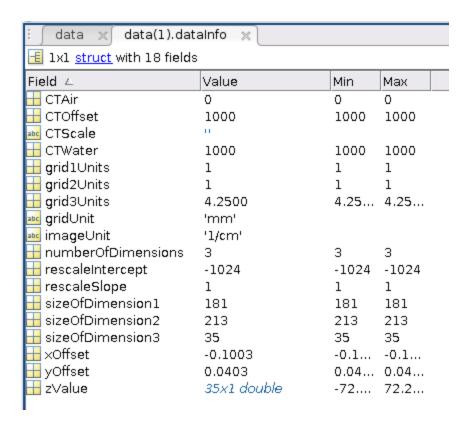

These data should be stored in a 1x2 structure named "data":

In the example folder in the github repository, there is a *.mat-file with a sample data structure file. You can use that data as a starting point and just change the data and relevant information for your own simulation.

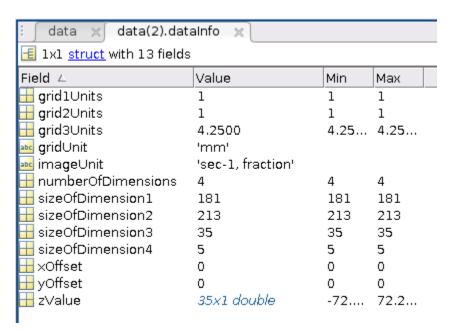

CT or mu-map

The dataInfo for the CT or mu-map should contain the fields as in the figure below. Currently, the grid units have to be in millimeters. For mu-maps, the unit should be 1/cm. The zValue is a vector with the mid slice positions in millimeters.

Parametric image

The dataInfo for the parametric image should look like below. The grid units should be in millimeters, and the rate constants should be in 1/sec. The zValue is a vector with the mid slice positions in millimeters.

Run a simulation

Once you have the input data structure set up properly according to above, you can start your simulation process.

First however, there are a few things you need to do:

1. You need to adjust all settings of the simulation according to your preference. Do this by opening "Dynamic_setSimParameters.m" and adjust the fields as you like.

>> open Dynamic setSimParameters.m

```
%% Simulation parameters
simSet = struct;
% input parameters
                        % CT scan's ID : should be automated
simSet.CTscanNum = 1;
simSet.PIMscanNum = 2;
                                    % Parametric image scan's ID : should be automated
simSet.PTscanNum = 3;
                                   % Dynamic PET image scan's ID : should be automated
% count data
simSet.countSens
                   = (265/324) *6.44; % 3D sensitivity (counts/kBq/s) (GE DLS)
simSet.SF = 0.289; % scatter fraction S/(T+S)
simSet.RF = 0.02; % randoms fraction R/(T+S+R)
% Dynamic settings
SimSet.1rame = frame; % Vector with frame times in sec.
simSet.dwellTime = diff(frame); % Frame lengths.
simSet.Cif = Cif: ° ...
                   % Vector with input function in Bq/cc. Either arterial input function.
simSet.CifScaleFactor = 1;
                                    % Scale factor to multiply the supplied input function with.
simSet.kineticModel = '2-Tissue'; % Desired kinetic model, '1-Tissue', '2-Tissue', 'FRTM', 'SRTM' or 'sumExp'.
% scanner charaterisitics
simSet.simSize = 165; % matrix size of reconstructed image
simSet.zFilter = [1 2 1]; % post recon Z-axis filter 3-point smoothing
% Heavy[ 1 2 1]/4, Standard[1 4 1]/6, Light[1 6 1]/8, None[0 1 0]
simSet.postFilter = 6; % FWHM in (mm) of post reconstruction filter. FWHM = 2*sqrt(2*log(2))*sigma.
simSet.iterNUM = 5; % number of iterations
simSet.subNUM = 16; % number of subscri
% image reconstruction definitions
% Biologic variability
simSet.addVariability = false; % Flag to add biologic variability or not
% Reconstructions
simSet.FBP_OUT = false;
simSet.OS_OUT = true;
simSet.OSpsf_OUT = false;
% number of replicate data sets
simSet.nREP
```

2. You then specify the input function to your model, a vector called "Cif". Should be the arterial input function for the 1-, and 2-Tissue models and sum of exponentials, and a reference tissue TAC for the FRTM and SRTM models, in unit (Bq/cc).

```
Cif = [Cif_1; Cif_2; ...; Cif_f-1]. f = number of frames.
```

- 3. You also need to specify the frames of your simulation in a vector called "frame", unit (sec). frame = [frameStart_1; frameEnd_1=frameStart_2; frameEnd_2=frameStart_3; ... frameEnd_f].
- 4. The final data you need is a vector with the average activity in unit (Bq/cc) per frame that you want. This scales the simulated sinograms which in turn determines the noise level.

 Cmean = [Cmean 1;Cmean 2;...;Cmean f-1].

To run a simulation, simply run:

```
>> Dynamic main(data, frame, Cif, Cmean)
```

(See section Matlab functions below). This adds a pristine (noiseless) dynamic image based on your parametric image and settings to your structure "data". It then simulates the dynamic PET from that dynamic pristine input. The data that is created is:

FBP4D 4D matrix with reconstructed dynamic FBP image.
OS4D 4D matrix with reconstructed dynamic OSEM image.

OSpsf4D 4D matrix with reconstructed dynamic OSEM image with PSF correction.

counts Structure with the pristine sinogram counts. countsNoise Structure with the noisy sinogram counts.

Matlab functions

To run dPETSTEP, you will also need to download the MATLAB functions from PETSTEP (found in the PETSTEP repository on github).

The MATLAB functions in dPETSTEP (found in the dPETSTEP repository on github) are the following:

addVariability2PIM.m

```
%| Adds variability to an existing parametric image (PIM). Represents biological diversity.
%| IH, 19/04/2016
용티
%| m
         = number of kinetic parameters.
% | nx,ny,nz = image dimensions.
용|
%| USAGE : pim_var = addVariability2PIM('pim',pim,'scale',10).
용티
% | INPUT : pim
                  2 or 2D parametric image, one vector per voxel. Rate constants in unit
                   (s^-1).
옿ㅣ
용|
                  pim = [nx*ny*nz*m].
용 |
         scale Scalar with amount of variability, sigma = pim/scale.
용티
                   (higher scale-->less variability).
%| OUTPUT: pim var 2 or 2D variablility (~noise) parametric image, one vector per voxel. Rate
용 |
                   constants in unit (s^-1).
용|
                   pim_var = [nx*ny*nz*m].
욯I
```

calculateWeights.m

```
.
% Calculates frame weights = 1/variance according to user specified model.
% IH, 19/04/2016
% f = number of frames
               - mid frame (time) column vector [f-1,1], unit (sec).
% INPUT:
        C - tissue TAC [f-1,1].

type - type of weighting, string 'w1', 'w2'...
         frameVar - frame variance, column vector [f-1,1].
        halflife - halflife of nuclide in (sec), scalar.
윻
용
        Available weight model types are:
         'ones' : uniform weighting (vector of ones)
용
         'w1'
             : 1/frameVariance
8
        'w2' : decayFactor^2
ş.
        'w3' : decayFactor * 1/(frameLength*TAC)
         'w4' : frameLength * exp(-lambda*t) / TAC
         'w5' : frameLength * exp(-lambda*t)
% OUTPUT: w
              - weight vector [f-1,1].
```

convertCT2mumap.m

createDynamicPETfromParametricImage matrix.m

```
%| Creates a 4D dynamic image of a 4D matrix with kinetic parameters (parametric image), using
% a given blood input function or reference TAC, and frame vector. PIM = parametric image.
& I
%| IH, 19/04/2016
& I
% | N = no of kinetic parameters.
%| f = no of frames.
% I
%| USAGE : dynamicImage = createDynamicPETfromParametricImage_matrix('paramImage',paramImage,... |
                                                           'model','2Tissue',...
욯I
                                                           'Cif', [cif_1 cif_2...cif_f-1],...
ξ.
% I

%"recon_osemPSFSimData_nonUniformSliceSens"
Reconstructs PET-like images via OSEM w/ psf for non-uniform axial sensitivity
% CRS, 08/01/2013
% IH, 19/04/2016
%Usage:
% [OS] = recon_osemPSFSimData_nonUniformSliceSens(nFWPTtotal,
RS, CTAC, PSF, POST, wcc, radBin, tanBin, simSize, zSlice, iterNUM, reconType)
    nFWPTtotal = Projection data
    RS
૾ક
           = scatter + random projection reference data
    CTAC
            = CT attenuation correction data
ક
    PSF
            = FWHM of PSF
ş
    POST
            = FWHM of post filter
옿
            = "Well-counter correction"
용
    WCC
    radBin = radial bins
    tanBin = projection bins
용
    simSize = Final image size
용
    zSlice = number of slices
용
    iterNUM = number of iterations
```
